

Bacterial Physiology Week 3 Part 2 – The Cell Wall

Antibiotics and disinfectants are used to kill bacteria or inhibit their growth

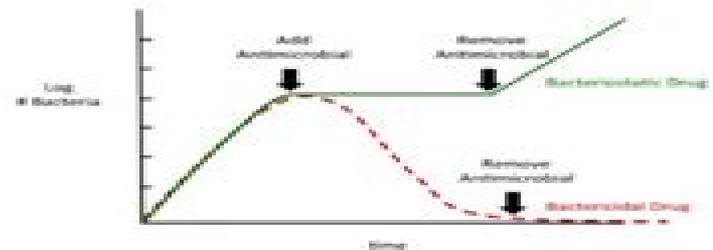

- Our cells share a lot of characteristics with bacteria: we both have phospholipid bilayer membranes, DNA, RNA, ribosomes, and proteins, among others
- Penicillin prevents bacteria from building a cell wall
- Chloramphenicol and tetracycline inhibit protein synthesis
- Rifampicin inhibits RNA transcription
- Alcohol dissolves the bacterial membrane

Most antibiotics work by binding to proteins.

If the activity of an enzyme is interrupted by an antibiotic, then the cell loses that function.

- Bacteriostatic – the growth of the bacteria is inhibited, but the bacteria are not necessarily killed
- Bactericidal – the bacteria are killed

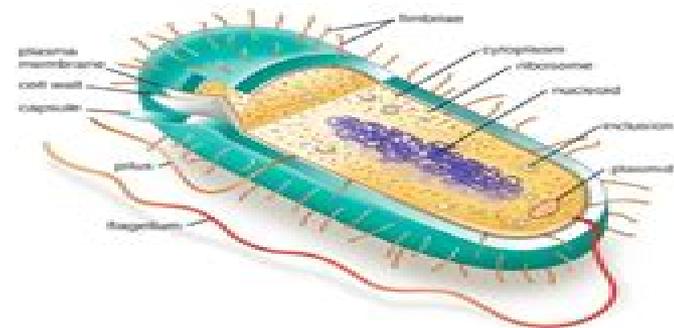

There are six primary antibiotic targets in bacteria:

- 1) Cell membrane
- 2) Cell wall synthesis
- 3) DNA replication
- 4) RNA synthesis
- 5) Protein synthesis
- 6) Metabolism (folic acid synthesis)

Plus some other special cases

- Biofilm formation
- Flagella/pili
- Quorum sensing
