

BONY FISH (Class Osteichthyes)

INTERNAL ANATOMY

The largest group of fish are the bony fishes and includes reef, sea horses and rayfish. The total number of species of bony fish is thought to be more than 13,000.

As the name suggests, bony fish have a bony skeleton with a protective bony plate called the operculum covering the gill cavity and a single external gill slit.

Gills

Fish have a simple, single loop circulatory system where blood flows from the heart to the gills, and then to the rest of the body. It is a closed loop through a series of veins and arteries.

Gills consist of gill arches, which are a supporting structure, gill rakers that remove solid material, and gill filaments, a net which gas exchange occurs. Gas exchange is the diffusion of oxygen from the water into the blood vessels of the filaments, with carbon dioxide diffusing out of these blood vessels into the water passing over them.

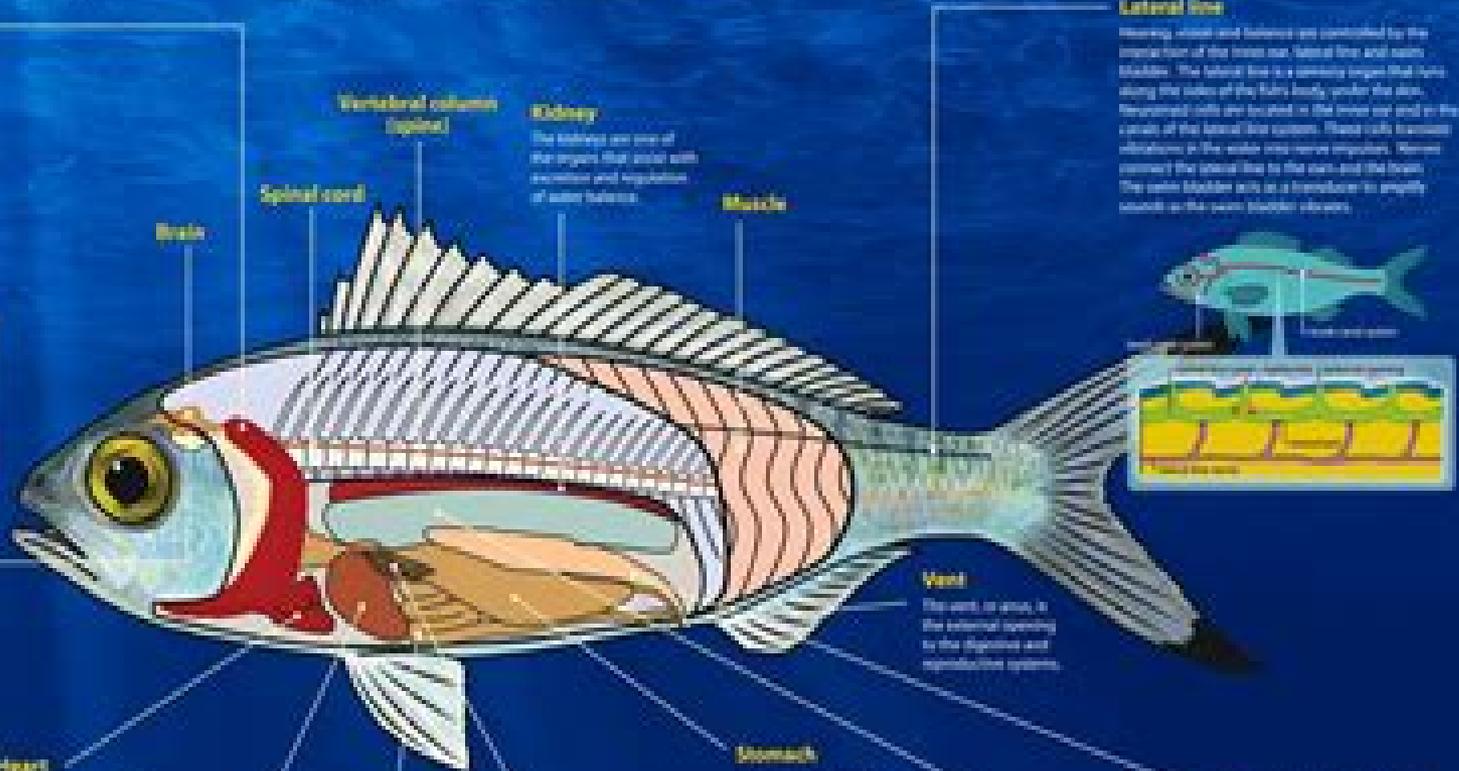

Cycloth

While fish don't have ears like humans, they "hear" sounds with their own environment and can tell what direction it is coming from. Fish might not have ear bones, but in sounds that instead use their whole bodies to pick up vibrations that sounds make.

Age and growth

Scientists can determine the age of bony fish by studying their otoliths, or fish bones. They white and clear bands of calcified material are laid down in the otolith, similar to growth rings in a tree. The growth bands are counted under a microscope to determine the age of the fish.

Heart

The heart is a muscular organ which pumps blood throughout the body.

Similar to sharks, blood is circulated by a 2+ chambered heart and passes through the gills where it loses carbon dioxide and receives a fresh supply of oxygen prior to entering the remainder of the body.

Liver

The liver produces enzymes (chemicals) to aid in digestion. It is also a storage area for fat, blood sugars and vitamins and breaks down toxins and old blood cells for excretion or recycling.

Intestine

The intestine is the main site of digestion and absorption. In a general rule, fish with short intestines are opportunistic (eat what they can) and those with long, coiled intestines are herbivores (plant eating), or filter-feeding (straining materials from water to break down).

Pyloric caecum

Finger like pouches attached to the intestine immediately following the stomach, which are believed to have a digestive and/or absorption function.

Stomach

The stomach is where digestion commences. The main components of the digestive system include the fish, stomach, intestine and pyloric caecum.

Feeding

Like sharks and rays, fish have a low key digestive system. Food enters the mouth and travels via the oesophagus to the stomach. From the stomach it is passed into the intestine for further digestion. Digested wastes are eliminated from the intestine via the anus.

Lateral line

Hearing, vision and balance are controlled by the interaction of the inner ear, lateral line and swim bladder. The lateral line is a sensory organ that runs along the sides of the fish's body, under the skin. Receptor cells are located in the inner ear and in the canals of the lateral line system. These cells transmit vibrations in the water into nerve impulses. Nerves connect the lateral line to the brain and the brain. The swim bladder acts as a transducer to amplify sounds in the swim bladder chamber.

Vent

The vent, or anus, is the external opening to the digestive and reproductive systems.

Reproductive organs

The reproductive organs of fish are referred to as gonads. These organs are usually paired. Female gonads (ovaries) produce eggs and are usually pink, red or orange in colour and are covered in numerous blood vessels. Male gonads (testes) produce sperm and are usually white (white) or grey in colour.

Reproduction

The majority of bony fish reproduce by external fertilisation of their eggs and have a pelagic larval stage. Most bony fish produce thousands (and in some fish, millions) of eggs each year.
