

Early Detection of Developmental and Behavioral Problems

Frances Page Glascoe, PhD*

OBJECTIVES:

After completing this article, readers should be able to:

1. List the percentage of children who drop out of school and have undetected disabilities or known environmental risk factors.
2. Describe the ways in which early intervention is effective.
3. Delineate methods of detecting disabilities and development delays.
4. Describe the percentage of children in whom assessment tools can detect disabilities correctly.
5. Determine how often children should undergo developmental testing.
6. Describe the role of parents in detecting and addressing developmental and behavioral problems.

Epidemiology and Issues for Clinicians

Approximately 15% to 18% of children in the United States have developmental or behavioral disabilities. An additional 7% to 10% experience substantive school failure and drop out before completing high school. Overall, one in four children has serious psychosocial problems. To ensure that these children are detected early and their difficulties addressed, the American Academy of Pediatrics' Committee on Children with Disabilities recommends that pediatricians use validated screening tools at each health supervision visit.

Many pediatricians find it difficult to comply with this recommendation because of minimal reimbursement, young patients' limited compliance with requests to stack blocks or answer questions, time constraints, and concerns about the accuracy and length of well-known screening tools. Finally, children who are at environmental risk for developmental delays and subsequent school failure due to poverty, limited parental education, and similar risk factors do not always receive health supervision visits. Accordingly, they are unavailable at times when pediatricians typically are most vigilant in their search for developmental problems.

UNDERDETECTION

Most physicians depend on clinical judgment rather than screening tools. Unfortunately, research shows that clinical judgment detects fewer than 30% of children who have mental retardation, learning disabilities, language impairments, and other developmental disabilities. Clinical judgment also identifies fewer than 50% of children who have serious emotional and behavioral disturbances. Use of improved classification systems, such as the Primary Care version of the American Psychiatric Association's *Diagnostic and Statistical Manual (DSM-PC)*, may lead to higher identification rates, although research on this possibility is needed.

Why is the identification of psychosocial problems so poor? One culprit may be the developmental checklists typically embedded in pediatric encounter forms. Although these contain different tasks for patients of different ages, checklists are neither validated nor standardized. None provides proof that specific items measure important skills, and none has scoring criteria that enable clinicians to determine how many failed items is too many. Should the child who misses one out of the typically four or five tasks listed (eg, puts two words together, stands on one foot for 10 seconds) be referred? Two of five? Three of five? No one knows. Physicians never would use such haphazard and unproven methods for screening

blood lead levels, thalassemia, or hypothyroidism. Why do we accept less for development and behavior?

Even when screening tests are used, many clinicians administer them only after noticing a problem, rather than using them with asymptomatic patients, as recommended. Other contributions to limited detection include nonstandardized applications of standardized measures, such as administration of only selected items on the Denver Developmental Screening Test-II. These violations to test validity also may leave professionals without clear information on children's developmental and behavioral status.

THE CONTRIBUTION OF DEVELOPMENT

The nature of developmental problems adds to the challenges of early detection. Young children's symptoms are often subtle and difficult to discriminate from normal development. For example, most children who have disabilities talk, but they may not talk well. They usually read, but may not read well. Similarly, a child who has serious attentional or behavioral problems may be obedient and focused during a brief office visit. Few children who have disabilities are dysmorphic or show other symptoms likely to be apparent on physical examination.

Development is also a "moving target." Developmental disabilities develop just as normal development does. It is impossible to determine that a 12-month-old child has a language impairment until vocabulary or word combinations fail to emerge or emerge only in an attenuated state. Learning disabilities and attention deficit disorder rarely are detected until 4 to 7 years of age, when children initially are exposed to reading instruction and other structured academic tasks. Not apparent until 2 to 3 years of age is the adverse impact of environmental risk factors, including single parenthood, less than a high school education for the parent, limited social
