

Advances in Data Management: Parallel and Distributed Query Processing

The basic foundations of parallel query evaluation are the **splitting** and **merging** of parallel streams of data:

Data streams arising from different disks or processors provide the input for each operator in the query.

The results being produced as an operator is evaluated in parallel over a set of nodes need to be merged at one node in order to produce the overall result of the operator.

This result set may then be split again in order to parallelise subsequent processing in the query.
